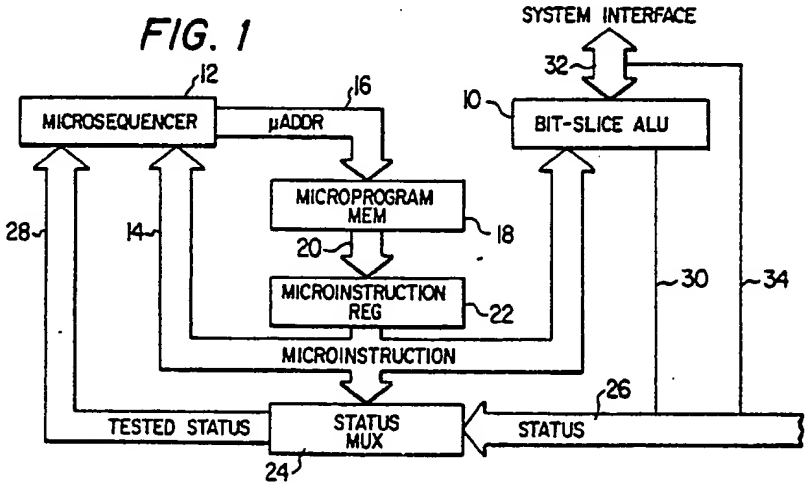
(54) Alu for a bit slice processor with multiplexed bypass path.

(57) A bit slice ALU for a bit slice processing system includes an ALU (36) which has data input from a register file (50) onto input buses (40) and (38). The output of the ALU (36) is input to a multiplexer (86) which has the other input thereof connected to a bypass bus (71) for bypassing data around the ALU (36). The multiplexer (86) is controlled by a decode logic circuit (108) for selecting the output of the ALU (36) or the bypass bus (71). A decision logic circuit (90) is provided for determining status information of the data to be processed and outputting a feedback signal on a line (112) to the decode logic circuit (108) for the multiplexer (86). The decision logic circuit (90) operates in parallel with the processing operation of the ALU (36) such that either the processed data can be selected or the bypassed data on the bus (71) can be selected. This significantly increases the speed of the processing system for select functions.

FIG. 1



EP 0 239 276 A2

ALU FOR A BIT SLICE PROCESSOR WITH MULTIPLEXED BYPASS PATH

TECHNICAL FIELD OF THE INVENTION

The present invention pertains in general to bit slice systems and, more particularly, to the processing of data through the ALU section.

BACKGROUND OF THE INVENTION

A bit slice system provides a designer with the tools to customize a processor to the needs of a given application. The bit slice architecture utilizes a bit slice processor which is comprised of a microsequencer and an expanded bit slice arithmetic logic unit (ALU). The microsequencer is combined with a microprogram memory and a microinstruction register to provide control codes for the bit slice ALU. This type of a processor is effectively a computer for disposal within a more sophisticated computer architecture. With the bit slice system, the designer can define the details of the system operation, including the instruction set to be implemented. This allows the designer to deviate from the preset instruction set which is common to most processors.

The bit slice ALU is a fundamental part of the system. This element is designed so that it can be connected to similar elements to provide an ALU of any desired word width. Central to the ALU slice is that its operation can be expanded to any number of bits by interconnection of like ALUs. For example, if an ALU with eight bits per circuit is utilized, four circuits would form the ALU for a thirty-two bit processor. The carry and shift lines provide communication between ALUs so that multiple bit arithmetic operations can be performed.

The processing speed of the bit slice system is a function of many factors such as the speed of the various components, delay times and generated instructions, etc. One limiting factor is the processing speed of the ALU. This processing speed is a function of the ALU circuitry and, more importantly, the particular type of operation that is being performed by the ALU under the control of the various instructions. In performing a simple operation with the ALU, it is necessary to input an instruction into the bit slice ALU for the desired function, output operands from a local register file and then process the data in accordance with the predetermined function. The processing speed of the bit slice ALU is determined by the slowest operation to be performed. For example, if the absolute value of a number is taken, this will require the ALU to directly throughput the word if the sign bit indicates a positive number, and to take the two's complement if the sign bit indicates a negative number. This operation requires an additional logic step to determine what the magnitude of the sign bit is. Therefore, additional logic is provided for determining the status of the sign bit and the control signals generated to alter the operational mode of the ALU for processing of the data.

In conventional units, data is first processed through status logic circuitry to determine the processing mode for the ALU and then the data is processed through the ALU. This is a serial mode which, for the slowest operation, results in a first predetermined amount of delay for determining the processing mode of the ALU and a second and sequential predetermined amount of delay for processing the data through the ALU. In order to increase the speed of the bit slice ALU, it is necessary to minimize the delay for certain operations which require long delays to determine status of the information, and generate control information for the ALU in a serial processing manner.

SUMMARY OF THE INVENTION

The present invention disclosed and claimed herein comprises a bit slice processor with two processing paths selectable in response to determining the status of the data being processed. The parallel processing paths comprise an arithmetic logic unit having a data input and a data output and a bypass bus connected to the input data. The output of the ALU and the output of the parallel data bus are connected to the input of a multiplexer. The multiplexer is controlled to select either the output of the ALU or the output of the parallel data bus. Status decode logic is provided for determining the status of input data in accordance with a predetermined data processing function, and generating a status signal in response to the status determination to control the multiplexer. Decode logic is provided for receiving instruction information to

select one of the arithmetic logic functions in the ALU. Multiplex decode logic circuitry is provided for receiving the instruction information and the status signal and controlling the multiplexer to select the output of the ALU or the output of the parallel data bus in accordance with the data processing function.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention and the advantages thereof, reference is now made to the following description taken in conjunction with the accompanying Drawings in which:

FIGURE 1 illustrates a schematic block diagram of a bit slice processor;

FIGURE 2 illustrates a schematic block diagram of a bit slice ALU;

FIGURE 3 illustrates a schematic block diagram of the ALU and the bypass path for increasing processing speed;

DETAILED DESCRIPTION OF THE INVENTION

Bit Slice Processor Operation

With reference to FIGURE 1, there is illustrated a schematic block diagram of a bit slice processor which is part of an overall bit slice system (not shown). The bit slice processor consists primarily of a bit slice ALU 10 and a microsequencer 12. These two elements operating in conjunction form a microprogrammed processor which operates in the background of a main memory processor program (not shown). The main program consists of the same type of macroinstructions that any processor executes. The microprogram is stored in the microsequencer 12 and is operable to control each element within the processor to determine the particular sequence of instructions that are carried out. The microprogram is primarily directed toward elemental details of each type of ALU operation, memory reference, and I/O operation on a step-by-step basis.

To fetch and execute a single macroinstruction from main memory (the task of every processor), the bit slice processor must execute two or more sequences of microinstructions from the microprogram stored in the microsequencer 12. First, it executes a sequence of microinstructions to perform the instruction fetch and decode operations. Then, it executes the appropriate sequence of microinstructions that will implement the macroinstruction.

The microsequencer 12 and bit slice ALU 10 are interfaced with the microinstruction bus 14 which is a bidirectional bus. In addition, the microsequencer 12 outputs a microaddress on a microaddress bus 16 to a microprogram memory 18. The microprogram memory 18 has stored therein the microinstructions, which are output on a bus 20 to a microinstruction register 22 for storage therein. The microinstruction register 22 is interfaced on the output thereof with the microinstruction bus 14.

A status multiplexer 24 is provided for interfacing between the microinstruction bus 14 on one input and a status bus 26 on another input. The output of the status multiplexer 24 is a tested status bus 28 which is input to the microsequencer 12 to provide status information. The status bus 26 receives a status input from the ALU on lines 30. The bit slice ALU 10 interfaces with a system interface bus 32 which also interfaces with the status bus 26 through lines 34.

In operation, the bit slice ALU 10 is connected to the system interface bus 32 since this block performs all data and address manipulations. The status information of the bit slice ALU 10 is interfaced with the microsequencer 12 so that the microsequencer can implement any needed conditional branch or jump operations by the output of appropriate microinstructions. The control lines that define the operation of the bit slice ALU 10 must come from the microinstruction bus 14 since it defines what operation each element of the system is performing at each point in time.

The control code for the bit slice ALU 10 makes up part of the microinstruction code, or microcode for short. Another part of the microcode must define the memory and input/output operations, such as memory read, memory write, input Read and output Write, that are to occur. The number of bits that must be devoted to the ALU control code and the memory control code depends on the ALU bit slice function code length, and the number of memory input/output control signals that the need to be generated. As described above, the microprogram memory 18 contains all of the microcode with the microinstruction register 22 holding the microcode for the microoperation that is currently being performed.

The microsequencer 12 determines which microinstruction is to be executed next, and must send this address to the microprogram memory 18. Normally, the next instruction is located immediately after the current instruction being executed, just as it is in the main computer program in main memory. Thus, the sequencer usually adds one to the present microaddress to get the next microaddress. In some cases, the microsequencer 12 must perform a branch or subroutine jump within the microprogram. The address for a jump to the next microinstruction to be executed must come from either the current microinstruction, or it must be an address generated as a result of the main instruction code or an interrupt condition. The branch address is generated by either a portion of the microcode and the microinstruction register 22, or it is generated by an internal interrupt vector circuit (not shown). The microsequencer 12 is therefore instructed as to whether to execute a branch, a subroutine jump a subroutine return, or simply increment to the next microinstruction address in the microprogram memory 18.

Bit Slice ALU

Referring now to FIGURE 2, there is illustrated a schematic block diagram of the bit slice ALU 10. The bit slice ALU 10 includes an arithmetic logic unit (ALU) 36 which provides the processing capability of a conventional ALU. The ALU 36 has two inputs which are provided on an eight-bit wide S-bus 38 and an eight-bit wide R-bus 40. The S-bus 38 is connected to the output of a multiplexer 42 and the R-bus 40 is connected to the output of a multiplexer 44. Multiplexers 42 and 44 each have one input thereof connected to eight-bit buses 46 and 48, respectively, which are connected to two outputs from a register file 50. The multiplexer 42 has two remaining inputs, one of which is connected to an eight-bit bus 52 and the other of which is connected to an eight-bit bus 54. The multiplexer 44 has a second input which is connected to a data bus 56. Data buses 52 and 56 allow for input of two data words, each eight bits in length.

The output of the ALU 36 is connected to the input of an ALU shift circuit 58 through an output bus 59 and also to the input of a Multiply-Quotient shift circuit 60. The output of shift circuit 58 is connected to a Y-output through a gated buffer 62 through a bus 64. The bus 64 is also connected to one input of a multiplexer 66, the other input of which is connected to the output of buffer 62. The buffer 62 has the output thereof connected to the Y-output to provide an output for the bit slice ALU 10. The output of multiplexer 66 is connected to the data input of the register filer 50.

The shift circuit 60 has the output thereof connected to the input of a clocked register 68 through a bus 69, the output of which is connected to bus 54 for input to both the multiplexer 42 and also to the second input of the shifter 60. A divide flip-flop 70 is also provided for aiding in some of the processing operations of the bit slice ALU 10.

The input bus 38 on the ALU 36 has a bypass bus 71 for connecting the bus 38 with a second input on the ALU shift circuit 58. The shift circuit 58 is controlled by an external control and internal decode circuitry (not shown) to select the output of the ALU 36 or the bus 71 and shift it one place to the right, one place to the left or pass it directly therethrough. The operation of this bypass bus 71 will be described in more detail hereinbelow and comprises an important aspect of the present invention. The ALU 36 is a conventional circuit and is similar to the circuitry utilized in a device of the type 74LS181 manufactured by Texas Instruments, Inc.

Register file

The register file 50 is operable to store sixteen eight-bit words and has the capability to output two digital words or operands therefrom which are addressed by an A-address that is input on an A-address bus 72 and a B-address that is input on a B-address bus 74. The register file 50 also has the capability of being written back into through a Write address which is input on a C-address bus 76. In addition, the Write address input can be multiplexed to receive the address from the B-address bus 74 through multiplexer 78. As will be described hereinbelow, the register file 50 has a data latch for interface with the feedback bus 67

and a Write address latch for interface with the Write address output by multiplexer 78. The Write address latch is controlled by a Write Enable signal on line 80 which is input to an AND circuit 82, the AND circuit 82 being clocked by a clock signal. The register file also has the capability to output data on data buses 52 and 56 through three state enable buffers 83 and 84, respectively.

In operation, the register file 50 can provide two operands to the ALU 36 or two operands can be eternally input on the data buses 52 and 56 to the ALU 36. The ALU output is then sent through a double precision shifter consisting of ALU shifter 58 and the MQ shifter 60. These shifters help perform bit shifts and multiplications and divisions. The output of the ALU shifter 58, which can be unshifted or shifted ALU data, can be stored back in the register file 50 through control of multiplexer 66 and/or output to the external Y-bus. In double precision (16 bit) shifts and in multiplications, partial result components are stored in the MQ register.

The bit slice ALU of FIGURE 2 has additional inputs which are described in Table 1 as follows.

TABLE 1 - PIN DESCRIPTIONS

NAME	INPUT/OUTPUT	DESCRIPTION
$\overline{WE}$	Input	Register file (RF) write enable. Data is written into RF when $\overline{WE}$ is low and a low-to-high clock transition occurs. RF write is inhibited when $\overline{WE}$ is high.
B3-B0	Input	Register file B port read address select. (0 = LSB)
$\overline{OEB}$	Input	DB bus enable, low active.
DB7-DB0	Input/Output	B port data bus. Outputs register date ($\overline{OEB}$=0) or used to input external date ($\overline{OEB}$=1). (0 = LSB)
Y7-Y0	Input/Output	Y port data bus: Outputs instruction results ($\overline{OEY}$=0) or used to input external data into register file (OEY = 1).

$\overline{OEY}$	Input	Y bus output enable, low active.
PPP	Input	Package position pin. Tri-level input used to define package significance during instruction execution. Leave open for intermediate positions, tie to V_{CC} for most significant package, and tie to GND for least significant package.
SSF	Input/Output	Special shift function. Used to transfer required information between packages during special instruction execution.
ZERO	Input/Output	Device zero detection, open collector. Input during certain special instructions.
$\overline{P}$/OVR	Output	ALU active low propagate/ instruction overflow for most significant package.
$\overline{G}$/N	Output	ALU active low generate/negative result for most significant package.
C_n+8	Output	ALU ripple carry output.
$\overline{SIO7}$	Input/Output	Bidirection shift pin, low active.
$\overline{QIO7}$	Input/Output	Bidirection shift pin, low active.
$\overline{QIO0}$	Input/Output	Bidirectional shift pin, low active.
$\overline{SIO0}$	Input/Output	Bidirectional shift pin, low active.

C_n	Input	ALU carry input.
I0-I7	Input	Instruction inputs.
V_{CC2}		Low voltage power supply (2 V).
V_{CC1}		I/O interface supply voltage (5 V).
$\overline{EA}$	Input	ALU input operand select. High state selects external DA bus and low state selects register file.
GND		Ground pin.
DA0-DA7	Input/Output	A port data bus. Outputs register file date ($\overline{EA}$ = 0) or inputs external data ($\overline{EA}$ = 1).
CK	Input	Clocks all synchronous registers on positive edge.
C3-C0	Input	Register file write address select.
A3-A0	Input	Register file A port read address select.
$\overline{OEA}$	Input	DA bus enable, low active.
SELY	Input	Y bus select, high active.
EB0, EB1	Input	ALU input operand selects. These inputs select the source of data that the S-multiplexer provides for the S-bus. Independent control of the DB bus and data path selection allow the user to isolate the DB bus while the R-ALU continues to process data.
GND		Ground pin.

Parallel Processing

Referring now to FIGURE 3, there is illustrated a schematic block diagram of the ALU 36, the ALU shifter 58 and the bypass bus 71 with associated circuitry to more clearly illustrate the operation of the ALU 36. The ALU shifter 58 is comprised of a multiplexer 86 which has a first input for receiving the output of the ALU 36 through the bus 59 and a second input for receiving the output of the bypass bus 71. The output of multiplexer 86 is input to an L/R shifter 88 which is operable to shift left by one bit, right by one bit or to pass the data directly therethrough. The output of the L/R shifter 88 is connected to the bus 64. The multiplexer 86 receives fill logic from a fill logic circuit 89 through a shift fill bus 91 to provide fill bits for the shift operation.

A decision logic block 90 is illustrated which is comprised of various decision logic for generating status and control signals for feedback information. The decision logic block 90 receives the input data from the bus 38 through a connecting bus 92 and the input information from the bus 43 through connecting bus 94. Storage registers 96 are provided which are connected to the output bus 64 through a connecting bus 98 for storage of information from a previous processing cycle. These storage registers 96 are comprised of the divide flip-flop 70 and the MQ register 68. Although the storage registers 98 are illustrated as being connected to the output bus 64, the connecting bus 98 can also be connected directly to the output bus 59 from the ALU 36. The output of the storage registers 96 are input to the decision logic block 90 through a connecting bus 100.

The decision logic block 90 is operable to determine the status of all the information stored in the storage registers 96 or the status of the operands input to the ALU on buses 40 and 38. This information is utilized to determine whether the operands for the particular processing operation are to be passed through the ALU and processed thereby or are to be passed through the bypass bus 71, the multiplexer 86 controlled to select the appropriate path. The decision logic block 90 performs certain operations on the operands depending upon the particular processing operation. For example, the input operands may be processed by an exclusive OR function or the output of the ALU and one of the input operands may be processed by an exclusive OR function. The result sets the signal on the feedback bus to either a logic high or a logic low.

The ALU 36 is controlled by an ALU decode circuit 102 which is connected to the ALU by a control bus 104. The ALU decode circuit 102 receives an instruction from an instruction bus 106 which is interfaced with the instruction input I0-I7. In a similar manner, the multiplexer 86 and the multiplexer 88 are interfaced with a decode logic circuit 108 through control lines 110. The control lines 110 also control the fill logic circuit 89. The decode logic circuit 108 receives feedback information from the decision logic circuit 90 through a feedback control line 112. The decision logic circuit 90 is interfaced with a decode logic circuit 114 through a control line 116 and also with the status input through logic interface circuit 118. The logic interface circuit 118 is operable to receive the status information from the status pins on a bus 120 and is connected to the decision logic block 90 through a control line 122. The line 122 is also connected to the storage registers 96.

In operation, certain processing operations require information regarding the operands output by the register file 50 before it can be determined whether the data is to be processed by the ALU or the data is to be passed through the bypass bus 71 to the multiplexer 86. For example, if the absolute value of an operand is desired, it is necessary to first determine the magnitude of the sign bit and then to either directly output the data, if a positive sign bit is present, or process the data through the ALU 36 to provide the two's complement of that data, if the sign bit is negative. With the processing configuration of the present invention, the ALU 36 can be configured to provide the two's complement of the data and the decision logic 90 can determine the path of the data through control of multiplexer 86. Therefore, the maximum delay would be the time required to determine the magnitude of the sign bit and the time to feedback this information to the decode logic circuit 108 and select the appropriate bus 59 or 71. If the processing time for the ALU 36 to provide the two's complement was greater than the sum of the status determination time, that would be the limiting factor. This is a parallel operation where the ALU 36 is initially controlled by the instruction on bus 106 which sets the ALU in a mode that processes the data to provide the two's complement. Therefore, the ALU 36 is processing the data simultaneous with the status determination of the magnitude of the sign bit in decision logic block 90. This significantly increases the processing speed of the bit slice ALU in that the magnitude of the sign bit does not have to first be determined and then the ALU 36 controlled to process data after the decision is made.

In prior systems, there was no bypass path 71 available. This required the status of the data to be determined prior to setting the processing mode in the ALU 36. In the absolute value example described above, this would require first determining the magnitude of the sign bit and then controlling the ALU to either provide the two's complement or pass the data therethrough. Therefore, the processing time for the absolute value operation would be the sum of the delay time through the decision logic block 90, the feedback time to alter the ALU decode logic to change the mode to the correct mode in the ALU and the processing time of the ALU. This in effect would connect the control feedback line 112 in FIGURE 3 of the decision block 90 directly to the ALU decode circuit 102. In the present invention, the ALU 36 can be set in one mode and process data during the time that the decision is being made by the decision logic block 90 with the only delay thereafter being the time required to select either the bypass bus 71 or the output of the

ALU 36. This selection time is significantly faster than altering modes in the ALU 36, thus resulting in significantly increased speed for certain functions. Of course, it should be understood that there are functions provided by the ALU which realize no increase of speed with the bypass bus 71.

ALU Multiplexer

Referring now to FIGURE 4, there is illustrated a schematic block diagram of the multiplexer 86 and the L/R shifter 88 of FIGURE 3, wherein like numerals refer to like parts in the various Figures. The decode logic 108 is represented by a control read only memory (CROM) which receives on its input both instructions from the instruction bus 108 which consists of an eight-bit word and also status information on a status bus 120 and also the feedback line 112 from the decision logic block 90. The multiplexer 86 is configured as a group of AND logic gates having the inputs thereof interfaced with both the output bus 59 from the ALU 36 and the bypass bus 71, and also with the output from the CROM 108. The bus 59 provides an eight-bit output F0-F7 and bus 71 provides an eight-bit output $\overline{S0}$ - $\overline{S7}$.

The AND gates in multiplexer 86 are configured to provide a shift to the right, a shift to the left and a non-shift condition. Additional logic is provided to fill in the vacant bits. In a similar manner, AND gates are provided to provide a shift right, a shift left and a no shift condition for the information on the bypass bus 71.

A seven-input multiplexer circuit 130 has six inputs interfaced with the second through eighth bits F1-F7 of the bus 59 with the control input thereof connected to the SRX output of CROM 108. The multiplexer 130 provides a shift right function and is controlled by the SRX output. To provide the fill bit for the shift right function, an AND gate 132 is provided having one input connected to the bus 91 and the other input thereof connected to the output of the CROM 108 to the MSIOX line. A multiplexer circuit 134 is provided having seven inputs connected to the F0-F6 lines to provide a pass-through function with the control line thereof connected to the STX output of CROM 108. The bit $\overline{S7}$ of the bus 59 is selected with an AND gate 136 with the other input thereof connected to the MF7X output of the CROM 108.

A seven-input multiplexer circuit 138 is provided with the seven inputs thereof connected to the bits F0-F6, respectively, of bus 59 and the control input thereof connected to the SLX output of CROM 108 to provide a shift left function. The fill bit for the shift left operation is provided by an AND gate 140 which has one input thereof connected to the shift fill bus 91 and the other input thereof connected to the LSIOX output of the CROM 108.

The seven outputs of the multiplexer 130 are connected to the input of one of eight six-input OR circuits 142, each interfaced with one of the eight output lines $\overline{X0}$ - $\overline{X7}$ of the bus 64. The multiplexer 130 has its outputs connected such that the input lines F1-F7 are connected with the OR circuits 140 to associate it with output lines $\overline{X0}$ - $\overline{X6}$. The output of AND gate 132 is connected to the input of OR gate 140 to associate it with the $\overline{X7}$ line to provide a fill bit. The multiplexer 134 has the outputs thereof interfaced with the OR circuits 140 such that the lines F0-F6 are interfaced with OR circuits 140 to associate it with lines $\overline{X0}$ - $\overline{X6}$, respectively, and the AND gate 136 has the output thereof input to the OR gate 140 associated with the $\overline{X7}$ line. The multiplexer 138 has the outputs thereof interfaced with the OR circuit 140 such that the input lines F0-F6 are interfaced with the OR circuit 140 associated with the output lines $\overline{X1}$ - $\overline{X7}$ and the AND gate 140 has its output thereof connected to the OR gate 140 associate with the $\overline{X0}$ line to provide a fill bit for the least significant bit. Therefore, the multiplexers 130, 134 and 138 and the associated AND gates 132, 136 and 140 provide for a shift right, a shift left and a pass configuration, respectively.

A seven input multiplexer 144 has the inputs thereof interfaced with lines $\overline{S1}$ - $\overline{S7}$ of the bypass bus 71 and the control input thereof connected to the BSRX output of the CROM 108 to provide a shift right function. The output of multiplexer 144 is interfaced with OR circuits 142 such that the lines $\overline{S1}$ - $\overline{S7}$ are interfaced with lines $\overline{X0}$ - $\overline{X6}$, respectively. An AND circuit 146 is provided for fill logic and has one input thereof connected to the fill logic bus 91 and the other input thereof connected to the MCOX control line from the CROM 108. The output of AND gate 146 is connected to the input of OR circuit 142 associated with the $\overline{X7}$ output line. A seven input multiplexer 148 is provided having the inputs thereof connected to lines $\overline{S1}$ - $\overline{S7}$ and the control input thereof connected to a BPX control line from CROM 108. The outputs of multiplexer 148 corresponding to the input lines $\overline{S1}$ - $\overline{S7}$ are connected to the OR circuits 140 and associated with lines $\overline{X1}$ - $\overline{X7}$, respectively. An AND gate 150 is provided having one input thereof connected to the S0 line of bus 71 and the other input thereof connected to the BPX control line. The output AND gate 150 is connected to the input of OR circuit 140 to associate it with the $\overline{X0}$ output line. Multiplexer circuit 148 and AND gate 150 provide a straight through path for the bus 71.

Additional AND gates 152, 154 and 156 are provided for additional fill logic functions. The AND gate 152 has one input thereof connected to the fill logic bus 91, the other input thereof connected to the LQIOX output of the CROM 108 and the output thereof connected to the OR circuit 142 associated with the $\overline{X0}$ line. The AND gate 154 has one input thereof connected to the F7 line of the bus 59 through an inverter 158, the other input thereof connected to the MSRFX line from the CROM 108 and the output thereof connected to the OR circuit 140 associated with the $\overline{X7}$ line. The AND gate 156 has one input thereof connected to the fill logic bus 91 and the other input thereof connected to the MSRFX line from the CROM 108. The output of the AND gate 156 is connected to the OR gate 140 associated with the $\overline{X7}$ line.

Referring now to FIGURE 5, there is illustrated a schematic diagram of the logic for the multiplex circuits 130, 134, 138, 144 and 148. The logic circuit is configured with seven AND gates 160, each of which has one input thereof tied to a control line 162. The remaining inputs comprise seven separate input lines with the outputs thereof also being separate.

Referring now to FIGURE 6, there is illustrated a schematic diagram of the decision logic block 90 and the associated decode logic 114. However, it should be understood that some of the logic in the decision logic block 90 may be contained elsewhere since it can be distributed throughout the device. The decode logic 114 is a programmable logic array (PLA) which is formed of AND and OR logic. The AND logic is represented by horizontal and vertical lines which are criss-crossed with "dots" at selected intersections representing AND functions. These dots essentially represent the inputs of a multiple input AND gate with the vertical line representing the output. The second array in decode logic 114 is represented by the vertical lines of the AND logic array intersected with horizontal lines, this array representing an OR function. The horizontal line represent the output of a single OR circuit with the input thereof represented by "X's" at the intersection of select ones of the horizontal and vertical lines. The input to the AND portion of the PLA 114 is comprised of the eight bit instruction bus 106 and additional input signals on lines 168.

The PLA 114 provides a plurality of control output lines 170 from the output of the horizontal portion of the OR array. These provide for various control functions. The first eight of these control lines are each input to one input of an AND gate in an AND gate array 172. The output of each of the AND gates in the array 172 are input to one input of an eight-input NOR gate 174. The output of NOR gate 174 is input to one input of one of seven AND gates in an AND gate array 176. The other input of the AND gate associated with the NOR gate 174 is connected to one of the output control lines from the PLA 114. The output of each of the AND gates 176 in the AND array 176 are each input to one input of a seven input NOR gate 178. The output of NOR gate 178 comprises the inverted SSF signal which is input to the line 112 through a buffer 180. This is essentially the feedback signal from the decision logic block 90 of FIGURE 3.

Various input signals are provided to the decode logic block 90. These are the $\overline{S0}$ - $\overline{S7}$ outputs from the bypass bus 71, the R0-R7 outputs from the connecting bus 40 which are received on bus 94, the output from the storage registers 96 which are referred to as the MQ0-MQ7 outputs corresponding to the multiply-quotient register 68 and the divide flip-flops 70. The $\overline{S0}$ bit from bus 92 and the MQ2 bit from bus 160 are input to the two inputs of an exclusive OR gate 182, the output of which is connected to a NAND gate 184 in array 172. Additionally, the output of the exclusive NOR circuit 182 is input to one input of an OR gate 186, the other input of which is connected to the R0 signal and the output of which provides the shift fill logic signal $\overline{CRE}$.

The MQ0 and MQ7 bits from the bus 160 are input to an exclusive OR gate 188, the output of which is connected to the other input of a NAND gate 190 in array 172. The $\overline{S0}$ and $\overline{S7}$ bits from bus 92 are input to an exclusive NOR circuit 192, the output of which is connected to the other input of a NAND gate 194 in array 172. The divide bits $\overline{DIV0}$ and $\overline{DIV2}$ from the output of the divide flip-flops 70 are input to an exclusive OR gate 196, the output of which is connected to one input of an AND gate 198. The other input of the NAND gate is connected to the $\overline{DIVI}$ signal output from the divide flip-flops 70. The output of NAND gate 198 is connected to the other input of an AND gate 200. The $\overline{DIVI}$ signal is also input to the other input of an AND gate 202. The MQ1 input is inverted by an inverter 204 and input to the other input of an AND gate 206 in array 172. The $\overline{S7}$ bit is inverted with an inverter 208 and input to the other input of an AND gate 210 in array 172. The MQ7 signal is inverted with an inverter 212 and input to the other input of an AND gate 214 in array 172.

The R7 and F7 bits from the R-bus 40 and the ALU output bus 59, respectively, are input to an exclusive OR gate 216, the non-inverted output of which is connected to the other input of an AND gate 218 in array 176. The output of exclusive OR 174 is connected to the other end of an AND gate 220 in array 176. The inverted output of the exclusive OR gate 216 provides the QBT signal for the shift fill logic. The $\overline{DIV0}$ bit, the ALU carry output of the MCOUT and the $\overline{SUBADD}$ bit are input to a three-input exclusive OR gate 222, the output of which is connected to the other input of an AND gate 224 in array 176. The $\overline{DIVI}$ signal is inverted with an inverter 226 and input to one input of a three-input

OR gate 228, the output of which is connected to the other input of an AND gate 228 in array 176. The $\overline{DIVO}$, F7 and R7 signals are each input to one input of a three-input AND gate 230, the output of which is connected to one of the inputs of OR gate 228. The DIVO signal is input through an inverter 232 to one input of a three input AND gate 234, the F7 signal is inverted with an inverter 236 and input to one input of the AND gate 234, and the R7 bit is input to the remaining input of AND gate 234.

The ALU carry output of the MCOUT bit is input to one input of an exclusive OR gate 238, the other input of which is connected to the $\overline{CRY7}$ carry output of the ALU. The output of exclusive OR gate 238 is connected to the other input of an AND gate 240 in array 176.

The ALU carry output $\overline{CRY7}$ is connected through an inverter 242 to one input of a three-input exclusive OR gate 244, the other two inputs of which are connected to the ALU carry output COUT and the $\overline{BCD2}$ signal, respectively. The output of exclusive OR gate 244 is connected to the other input of a NAND gate 246 in array 176. The ALU carry output COUT and the $\overline{S7}$ bit from the bus 92 are input to two inputs of a three-input exclusive OR gate 248, the output of which comprises the SRF signal for providing shift right fill logic to the multiplexer circuit of FIGURE 4. The third input of exclusive OR gate 248 is connected to the output of a NOR gate 250, one input of which is connected to the subtract/add signal SUBADD. The other input of OR gate 250 is connected to the output of an exclusive OR gate 252. The two inputs of exclusive OR gate 252 are connected to the fourth bit of the instruction word and the R7 bit of the bus 94, respectively.

In operation, the $\overline{SSF}$ output from NOR gate 178 provides the control signal or feedback path to the decode logic 108 of FIGURE 4. This in turn controls the multiplexer 86 and L/R shifter 88. The feedback information provided from the circuit consists the divide flip-flop, the output of the storage registers 96 and also the outputs of either the R-bus 40 or the S-bus 38, the S-bus 38 comprising information on the bypass bus 71. This information is provided to control generation of the SSF in accordance with logic in the PLA 114.

In the above example for providing the absolute value function, it is necessary to determine what the magnitude of the sign bit is on the S-bus 38. If the magnitude of the sign bit indicates a negative number, it is necessary to process the data through the ALU 36 to provide the two's complement of the data and then select the output on the bus 59 with multiplexer 86. However, if the sign bit indicates a positive number, it is only necessary to process the data around the ALU 36 through the bypass bus 71. In so doing, it is not necessary to first determine the magnitude of the sign bit and then control the ALU 36 to either process the data to provide the two's complement or pass the data directly therethrough. As described above, this provides a sufficient increase in processing speed.

In the example of the absolute value, the instruction word is comprised of "00010010" corresponding to the bits I0-I7 of the instruction word input on bus 106 to PLA 114. Each of the instruction bits is input to the array directly and in an inverted form through inverters 254. The logic states for the absolute value are illustrated on the input line 258 to the array 114. In addition, a control signal MSP which is a tri-level input used to define package significance during instruction execution, is set low, resulting in a high on the input of an inverter 256. A vertical line 258 in the AND portion of the array 114 is illustrated as having "dots" at the intersections of the selected horizontal lines. For bits I0-I2, I4, I5 and I7, the connected intersections are for the inverted forms of the word whereas for bits I3 and I6, the intersections are connected at the non-inverted inputs.

In the OR portion of the array 114, a horizontal line 260 provides an OR function at intersections having "X's" disposed thereat. This results in an output on the one input to AND gate 210 in array 172. This in effect enables AND gate 210. The other input of AND gate 210 is connected to the output of inverter 208 which has the input thereof connected to the bit $\overline{S7}$. If $\overline{S7}$ is low, this indicates a positive number and the output of AND gate 210 goes high and the output of NOR gate 174 goes low which also forces the output of AND gate 220 low. The other input of AND gate 220 is connected to a horizontal line 262 which has an "X" at the intersection with vertical line 258, indicating an OR function. Therefore, the absolute value function results in the other input of AND gate 220 being high. Both AND gate 210 in array 172 and AND gate 220 in array 176 are "enabled" to allow the level of SSF to be determined by the status of the $\overline{S7}$ bit. The $\overline{S7}$ bit is the most significant bit or the sign bit for the data on bus 38. This bit determines the state of the control signal SSF. If the sign bit in bit $\overline{S7}$ is low, indicating a positive number, $\overline{SSF}$ is low selecting the bypass pass 71. For the other state, the ALU 36 is selected. Therefore, the circuitry of FIGURE 5 provides the decision logic necessary for decision logic block 90 and also the feedback information on line 112 to the decode block 108 The decode logic circuit 108 is comprised of the

information in the PLA 114 and also the logic in the arrays 172 and 176 and NOR gates 174 and 178. Although not shown, additional logic arrays are provided for both the ALU 36 and also for the multiplexer 86 and L/S shifter 88. This logic array is very similar to the array 114 in that it uses an array of AND gates and an array of OR gates.

In order to select a particular processing function for the bit slice processor of the present invention, it is only necessary to input an instruction on the instruction inputs I0-I7 to select the particular instruction. The following tables depict the instructions for the bit slice processor of the present invention. These instructions are arranged in five groups.

TABLE 2 - INSTRUCTION SET

GROUP 1 INSTRUCTIONS

INSTRUCTION BITS (I3-I0) HEX CODE	MNEMONIC	FUNCTION
0		Special (Note 1)
1	ADD	$R + S + C_n$ (Note 2)
2	SUBR	$\overline{R} + S + C_n$ (Note 2)
3	SUBS	$R + \overline{S} + C_n$ (Note 2)
4	INCS	$S + C_n$ (Note 2)
5	INCNS	$\overline{S} + C_n$ (Note 2)

In summary, there has been provided a bit slice processor with a processing section that provides parallel processing for some of the more complicated functions. The processing section includes an ALU which receives data on two inputs and is controlled by a decode logic to output the data after processing thereof. A parallel path is also provided between one of the ALU inputs and the ALU output. The output of the ALU or the parallel path is selected by a multiplexer and input to a left/right shifting circuit to provide a shifting function. Decision logic is provided for determining status information on the data to be processed with feedback information utilized to control the multiplexer. In this manner, the ALU can process the data during the time the decision logic is operating and decision logic can then select either the processed output data from the ALU or the bypass path. This additional bypass path increases the speed of processing for certain functions and the status information for selecting this path is determined in parallel with the actual processing through the ALU.

Although the preferred embodiment has been described in detail, it should be understood that various changes, substitutions and alterations can be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

Claims

1. A bit slice processor, comprising:
data input means for inputting data for being processed;
instruction input means for inputting instruction information to a select one of a plurality of predetermined data processing function;
primary processing means having a data input interfaced with said data input means for processing received data for output from a data output in accordance with one of a plurality of selectable arithmetic logic functions;
parallel processing means having a data input interfaced with said data input means for processing data in accordance with a predetermined arithmetic logic function;
said primary and parallel processing means receiving data from said data input means in processing the received data simultaneously;

multiplex means for receiving a multiplex control signal and selecting the input of either said primary or parallel processing means for output therefrom and under the control of said multiplex control signal;
status logic means interfaced with data being processing through the bit slice processor between said data input means and the output of said multiplexer means for determining the data status in accordance with the selected one of the predetermined data processing functions, said status means outputting a status signal in accordance with said predetermined data process functions and the instruction information received by said instruction input means;
first decode logic means for interfacing with said instruction input means for decoding the instruction information in accordance with the predetermined decode logic function to control said primary processing means to select one of the predetermined arithmetic logic functions and to control said status logic means to interface with the data at a select point in the processing thereof and generate the corresponding status signal; and
second decode logic means for interfacing with said multiplex means for interfacing with said instruction input means for receiving and decoding the instruction information and also receiving the status signal from said status logic means to control said multiplex means as a function of both the instruction information and the status of the data determined by said status logic means such that data can be processed by said primary processing means and said parallel processing means simultaneously while said status logic means is determining the status of the data and said multiplex means can select the output of either said primary or said parallel processing means such that size of determination and processing occurs in parallel.

2. The bit slice processor in Claim 1 where said data input means comprises:
a register file for storing input data;
input interface means for interfacing an external data port with said register file for input of data thereto;
access means for receiving an external address and accessing said register file for storage of data therein or retrieval of data therefrom; and
data output means for receiving access data to read from said register file for output therefrom.

3. The bit slice processor in Claim 1 wherein said primary processing means comprises an arithmetic logic unit.

4. The bit slice processor in Claim 1 wherein said parallel processing means comprises a bypass bus for connecting the output of said data input means to the corresponding one of the inputs on said multiplex means to allow data to pass therethrough.

5. The bit slice processor in Claim 1 wherein said multiplex means further comprises means for shifting the data to the left or the right in accordance with signals received from said first decode logic, shifting to the right or left determined in accordance with said predetermined logic function.

6. The bit slice processor of Claim 1 wherein said status logic means is interfaced with said data input means to determine the status of the input data in accordance with said predetermined data processing function, said status signal determining whether said multiplex means selects the output of said primary or the output of said parallel processing means.

7. The bit slice processor of Claim 1 wherein said status logic means is interfaced with the output of said ALU for results of a previous processing operation, said status signal determining the status of the data from the previous operation in accordance with the predetermined data processing function.

8. A bit slice processor comprising:
data input means for inputting data for being processed;
an arithmetic logic unit having a data input and a data output and for processing received data in accordance with one of a plurality of predetermined logic functions selectable by ALU control signals;
parallel processing means having a data input interfaced with said data input means for processing data in accordance with a predetermined arithmetic logic function;
said arithmetic logic unit and said parallel processing means simultaneously processing data from said input means;
multiplex means for receiving the output of said arithmetic logic unit and the output of said parallel processing means and selecting one of said outputs in response to receiving a multiplex control signal;
status logic means interfaced with said data input means for determining the status of said input data in accordance with predetermined status criteria, said predetermined status criteria selectable by status control signals, and status logic means generating a status feedback signal including the status of the input data in accordance with the predetermined status criteria selected by the status control signals;
multiplex control means for receiving mutliplex control signals and said feedback status signals and controlling said multiplex means to select either output of said ALU or the output of said parallel processing means in accordance with said multiplex control signals and said feedback status information such that for select ones of said multiplex control signal said feedback status signals determined whether the output of

said ALU is selected or the output of parallel processing units is selected by said multiplex means; and
instruction decode means for receiving and decoding instruction information to generate said ALU control signal, said multiplex control signals and said status control signals in accordance with a plurality of predetermined data processing functions each of said predetermined data processing functions selected by said instruction information.

9. The bit slice processor of Claim 1 wherein said parallel processing means comprises a data bus connected between said input means and said multiplex means.

10. The bit slice processor of Claim 1 wherein said status signal is comprises of signal having a first state and a second state, said first state corresponding to selection of the output of said arithmetic logic unit by said multiplex means and the said second state corresponding to selection of the output of said parallel processing means by said multiplex means.

11. The bit slice processor of Claim 7 wherein said multiplex means comprises a multiplexer having two inputs and one output.

12. The bit slice processor of Claim 7 wherein said instruction decode logic means comprises a programmable logic array.

13. The bit slice processor of Claim 7 wherein said data means comprises:
a data register file for storing a plurality of data words in predetermined storage locations;
access means for accessing a predetermined one of said storage locations in accordance with receiving an external address for storage of information in said register file or extraction of information from said register file; and
means for outputting data from said register file when data is extracted from said data register file, said data output to said arithmetic logic unit and said parallel processing means.

14. A method for processing the data in a bit slice processor comprising:
receiving input data for being processed;
receiving instruction information to select one of a plurality of a predetermined data processing functions;
processing the received input data in accordance with one of a plurality of selectable arithmetic logic functions, said arithmetic logic functions selectable by ALU control signals;
processing the input data in accordance with a predetermined parallel arithmetic logic function in with a predetermined parallel arithmetic logic function in parallel with processing of data with said selectable arithmetic logic function;
multiplexing the processed data by the selectable arithmetic logic function and the process data by the parallel arithmetic logic function in selecting only one of the parallel or selectable arithmetic logic functions for output in response to receiving a multiplex control signal;
determining the status of the processed data in accordance with the predetermined data processing function to determine whether the data is to be processed by the selectable arithmetic logic function or the parallel arithmetic logic function and generate a status logic signal indicating which of the parallel or selectable arithmetic logic functions are to be utilized;
decoding the instruction information in generating a plurality of control signals, the control signals operable to select one of the selectable arithmetic logic functions and control generation of the status logic signal; and
generating the multiplex control signal in response to receiving one of the control signals generated from decoding instruction information and receiving the status signal such that multiplex control signal is a function of both the status signal and the control signal generated from decoding of the instruction information.

15. The method of Claim 14 wherein the parallel step of processing data comprises passing the data through a bus such that a parallel processing arithmetic logic function does not effect the state of the data.

16. The method of Claim 14 wherein the step of processing the data with the selectable arithmetic logic function comprises inputting the data to an arithmetic logic unit having a plurality of arithmetic logic functions selected by a control signal.

17. The method of Claim 14 wherein the step of generating the status signals comprises providing a status signal with a first and a second state, the first state corresponding to selection of the selectable arithmetic logic function and the second state corresponding to selection of the parallel arithmetic logic function.

(54) **Alu for a bit slice processor with multiplexed bypass path.**

(57) A bit slice ALU for a bit slice processing system includes an ALU (36) which has data input from a register file (50) onto input buses (40) and (38). The output of the ALU (36) is input to a multiplexer (86) which has the other input thereof connected to a bypass bus (71) for bypassing data around the ALU (36). The multiplexer (86) is controlled by a decode logic circuit (108) for selecting the output of the ALU (36) or the bypass bus (71). A decision logic circuit (90) is provided for determining status information of the data to be processed and outputting a feedback signal on a line (112) to the decode logic circuit (108) for the multiplexer (86). The decision logic circuit (90) operates in parallel with the processing operation of the ALU (36) such that either the processed data can be selected or the bypassed data on the bus (71) can be selected. This significantly increases the speed of the processing system for select functions.
